Cancer is a group of diseases characterized by uncontrolled growth and spread of abnormal cells. Breast cancer has ranked number one cancer among Indian females with age adjusted rate as high as 25.8 per 100,000 women and mortality 12.7 per 100,000 women. Tamoxifen was discovered in 1967. It is on the World Health Organization's List of Essential Medicines, the most effective and safe medicines needed in a health system. In the present study, investigations is performed to study coating of silver nanoparticles.

INTRODUCTION
Breast cancer has ranked number one cancer among Indian females with age adjusted rate as high as 25.8 per 100,000 women. About 1.7 million new cancer cases are expected to be diagnosed in 2018. Cancer usually develops in older people; 87% of all cancers in the United States are diagnosed in people 50 years of age or older. In the US, approximately 40 out of 100 men and 38 out of 100 women will develop cancer during their lifetime. Tamoxifen drug has been used for the treatment for breast cancer. Hence the drug is chemically modified to treat breast cancer.[1]

MATERIALS AND METHODS

Collection of Drug
TAMOXIFEN (10mg) were bought from medical shop in Coimbatore, Tamilnadu, India.

Nano Particle Coating Tamoxifen Drug
Tamoxifen citrate nanoparticles (TNPs) were prepared by a multiple-emulsion solvent evaporation method, with some modifications of the reported methods.15–17 The compositions of the different formulations. Tamoxifen citrate and subsequently PLGA (85:15) (~200 mg) were dis-solved in 0.5 mL of methanol and 1.5 mL of dichloromethane mixture (phase 1). PVA was dissolved in water (2.5% weight per volume [w/v]) (phase 2), and 0.5 mL of phase 2 was added drop-wise into phase 1 with homogenization at an optimized speed (22,500 rpm) using a high-speed homogenizer. The prepared primary emulsion was then added slowly into 75 mL of 1.5% (w/v) PVA solution (phase 3) with a continuous homogenization (22,500 rpm), which produced a secondary emulsion. The secondary emulsion was then placed on a magnetic stirrer and stirred overnight for evaporation to remove organic solvent and solidification of the particles. The product obtained after lyophilization was kept overnight in a desiccator for the removal of the remaining moisture, then the lyophilized samples were stored in an airtight container at 4°C.[2]

Drug Characterization
Solution A was prepared by 0.4 gm of 2% Sodium alginate in 20 mL of distilled water. Solution B was prepared by 0.665 gm of 0.2 molar Calcium chloride in 30 mL of distilled water. Calcium chloride solution and sample is pipette and coated as capsules in sodium alginate solution and the capsules are filtered then made to dry for 24 hours. And it is used for the further observation.

FTIR Spectroscopy. FTIR Spectra were recorded on Shimadzu IR spectrometer (FTIR 8201, at room temperature within the wave number range of 4000 to 400 cm⁻¹ using KBr discs.

The copolymer was synthesized by opening the cyclic dimer rings of the monomers D,L-lactide and glycolide, in the presence of a tin octanoate initiator (0.02% over the total mass of monomers) and of the lauryl alcohol coinitiator (0.01% over the total mass of monomers. The copolymer was then kept in a heated vacuum oven at 60°C, for 24 hours. The efficient vacuum control, the absence of humidity in the reaction medium, coupled with adequate stirring, were keys to achieving a successful synthesis. The synthesized PLGA copolymer was then placed in hermetically sealed flasks in a refrigerator. The tin octanoate initiator was used in the PLGA polymerization reaction, for being quite reactive, of great use in the food and pharmaceuticals industries, and recognized by the FDA for this very use [3].

SEM-Scanning Electronic Microscopy

Encapsulation of the drug within the nanoparticles was confirmed by energy dispersive X-ray (EDX) analysis. It is a technique by which the elemental composition of the sample can be identified. The EDX analysis system works as an integrated feature of a scanning electron microscope. Briefly, lyophilized formulations were spread on the metal stub and platinum coating was carried out. The samples were then examined under a scanning electron microscope. From the samples, or from different areas of the sample, the elemental compositions were determined. The dry samples were spread on a conducting adhesive tape, pasted on a metallic stub. The morphologies of the tested samples were investigated and imaged with scanning electron microscope (SEM). This was accompanied by energy dispersive x-ray spectroscopy at an acceleration voltage of 15 kV.

The films were fixed on the surface of the sticky tape [4]. A scanning electron microscope model TM3000 tabletop microscope (Hitachi), at a voltage of 5.0 kV and at a working distance between 3 mm and 10 mm, was used for the SEM tests, and the obtained images were reprocessed using the TM3000 software. All samples were analyzed at room temperature (±20°C). There was no need for sample coating with gold, as this analysis was conducted under low vacuum [5].

DNA Damage Assay

Isolation of DNA for DNA Damage

Prepared 0.25g LB broth in 10ml, inoculated with E.coli and incubated at 37°C for 24 hours. The solution was centrifuged at 5000rpm for 5minutes, and collect the pellet.700 μl of saline EDTA (TE buffer), and added 20μl of isozyme, incubated at 37°c for 30 minutes, Added 150μl of 10° of SDS and incubated in water bath at 65°C for 15 minutes. Then added phenol, chloroform and isoamyl alcohol in the ratio of (180μl:160μl:10μl). Centrifuged at 12000rpm for 10 minutes. And the aqueous layer was collected. Added 40μl of sodium acetate and 1ml of isopropanol, centrifuged at 12000 rpm for 10 minutes. The pellet was collected and added 700μl of 100% ethanol, centrifuged at 5000 rpm for 5 minutes. And again the pellet was collected, added 500μl of 70% of ethanol. Centrifuged at 5000rpm for 5 minutes and final pellet was collected, and used for the DNA damage process. The sample was made to run on Agrose gel 1 μl of TE buffer was added in both isolated DNA and plasmid; 10 μl of Fenton’s reagent was added and kept for incubation for 3 hours at room temperature. Then, the DNA was viewed under UV Transiliuminator. [6]

RESULTS AND DISCUSSION

Tamoxifen is one of the oldest drug used to treat breast cancer. To improve efficiency, Tamoxifen PLGA Encapsulated Nano particles using alkyl method and anti cancer activity of breast cancer cell” are determined under the following heading:

Nanoparticle Coating Tamoxifen Drug

The coating of chemical activity shows that best concentration in synthesis of Nano particle coated tamoxifen drug was 80mg (s4) was found to be 0.097mg and observed at 260nm.

The synthesized Nano composite is smaller than 100 nm and exhibits fluorescence emission band around 440 nm upon excitation with 340 nm wavelength. In the meantime, the nanocomposite was loaded with a chemotherapeutic drug, doxorubicin to evaluate the drug loading potential of synthesized nanocomposite. Moreover, the as-synthesized nanocomposite showed good osteogenic properties for bone tissue engineering and also exhibited excellent selectivity and sensitivity towards Fe3+ ions [7].

The synthesis of nano particle result indicates a effective enteric coating and delay the drug release, with 32% acryl eze solution, is possible. The formulation developed can further be worked on. For identifying a best formulation for delayed release pellets of pantoprazole sodium [8]. The modified AuNP were characterized by different physicochemical techniques. It could demonstrate for the first time the adsorption of three drug layers to a nanoparticulate system. Furthermore, the adaptation of the LbL-technique resulted in drastically increased drug deposition efficiency. Furthermore, we developed a new and comfortable way to solubilize water-insoluble drugs in water [9].
**Drug Characterisation**

The particles are made to dry for 24 hours, and used for further process.

**SEM**

Figure shows that through SEM analysis the size of the Nano particle coated tamoxifen and the data obtained revealed that most particles exhibit spherical shape, either free or in clusters of aggregates. Nanogel morphologies were analyzed by Scanning Electron Microscopy (SEM) by placing a drop of nanoparticle sample on carbon stickers on aluminum stubs, drying and coated with gold, prior to visualization in a Olympus equipment. It revealed that most particles exhibit spherical shapes.

**Dna Damage Assay**

The present study reveals the capacity of sample against the damage cell. These results indicated that the surface charge plays an important role on cytotoxicity. Particles synthesized from MDI displayed a higher cytotoxicity than those synthesized from IPDI. Size and physicochemical properties of the particles may explain the higher degree of DNA damage produced by two tested formulations. In this way, a rational choice of particles’ constituents based on their cytotoxicity and genotoxicity could be very useful for conceiving biomaterials to be used as drug delivering systems. The study reveals that DNA damage can be measured as an indicator of genotoxicity using an antibody against phosphorylated H2AX. By combining specific antibody-based detection of DNA damage with a cytotoxicity indicator, both parameters can be measured simultaneously in the same cell.
CONCLUSION

This study reveals that the chemical modified Tamoxifen drug has ADME property which improves the metabolism of the body. Hence it can be developed to new modified drug for the treatment for breast cancer.
