INTRODUCTION

The tibia is the most commonly fractured bone of all the long bones of the body. No fracture in the body arouses more controversy regarding treatment than tibial fracture. Due to their frequency, topography, mode of injury and sometimes type of treatment, they have become source of temporary or permanent disability. (1) In recent years, Minimally invasive plate osteosynthesis (MIPO), a new technology developed under the guidance of BO rules is (2) has become widely accepted for treatment of periarticular fractures, Metaphyseal fractures, and certain diaphyseal fractures where intramedullary nailing is not indicated. (3) there has been evidence showing superiority of biological fixation over a stable mechanical fixation. (4) the use of MIPO prevents

1. Large surgical approach
2. Extensive soft tissue stripping
3. Disruption of periosteaal blood supply
4. Nerve palsies

More over MIPO shortened the union time after surgery and the period of rehabilitation. Thus , MIPO helps people back to work as soon as possible. (5)

MIPO is now widely used in long bone fractures, mainly in humerus, tibia and femur. Operative procedures and characteristics are distinctive in different fractures sites.

Fractures of the tibia still pose a challenge to the orthopaedic surgeon due to certain peculiarities like; tibia is a subcutaneous bone so more chances of open type of fracture, greater tendency of displacement of tibial fractures and increased chances of post-op infection. Due to its poor blood supply and less soft tissue coverage there is an increased incidence of delayed union and non union. Biological plating techniques are those in which blood supply to the fractured fragments is maximally preserved. (3) 

ABSTRACT

Background: The tibia is the most commonly fractured bone of all the long bones of the body. Due to its poor blood supply and less soft tissue coverage there is an increased incidence of delayed union and non union. Biological plating techniques are those in which blood supply to the fractured fragments is maximally preserved. Aims and Objectives: 1. To access the over all final functional results of patient and return to normal activity. 2. To evaluate the Union rate and the average time taken for fracture union with MIPO. Methodology: Study was conducted between December 2009 to November 2012. 168 adult patients of either sex with diaphyseal fracture of tibia (upper 2/3rd shaft) were the study group (Males 112 Females 56). Open fractures were excluded. Results: 168 cases of fracture of diaphysis of tibia were managed by dynamic compression plate using MIPO technique. Majority of the subjects were males 84% and the rest 16% were females. The study revealed that most of tibial diaphyseal fractures (68%) occurred in young adults ie less than 30 years of age. 59 cases were tibial shaft fractures,48 were mid1/3,44 were distal 1/3,9 were segmental,8 were isolated tibia fractures. The average duration of union of the fracture in mid shaft tibia was 8-12 weeks, upper 2/3 rd and lower 1/3 rd junction was 8-10 weeks, lower 2/3 rd and upper 1/3 rd junction is 8-10 weeks, segmental 14-16 weeks, isolated tibia 8-9 weeks.
• Improved rates of union.
• Decreased infection rate.
• Decreased need for bone grafting.
• Ideal technique for dealing with multiply injured patient.
• Early mobilisation of extremity possible.

Aims and Objectives
• To access the over all final functional results of patient and return to normal activity.
• To evaluate the Union rate and the average time taken for fracture union with MIPPO.

METHODOLOGY
Study was conducted between December 2009 to November 2012. 168 adult patients of either sex with diaphyseal fracture of tibia (upper 2/3rd shaft) were the study group (Males 112 Females 56). Open fractures were excluded.

All cases were assessed initially in emergency room and they were provided with first aid and splintage in order to make the patient comfortable and reduce the chances of displacement of fracture fragments and thus avoiding further complications. Baseline investigations were done so as to access the fitness of patient for anaesthesia.

Routine blood investigations, CT, Serum urea, Serum creatinine, Serum electrolytes, Urine (R/e), ECG and Radiograph of local part including knee and ankle joint (AP and Lateral view), MRI chest X-ray were taken.

Inclusion Criteria:
1. Transverse fracture, Oblique fracture, Spiral fracture.

Exclusion Criteria
1. Compound fractures with significant soft tissue damage.
2. Pathological fractures.
3. Intraarticular fractures.
4. Old fractures ie more than 2 weeks old.
5. Fractures with compartment syndrome or impaired circulation.

RESULTS
168 cases of fracture of diaphysis of tibia were managed by dynamic compression plate using MIPO technique in this series over a period of three years. About 28% of the patients in his study have been found to be associated with other injuries signifying that fracture tibia is usually involved in Polytrauma patients. 52% of the cases have been operated within a period of 6-10 day’s from injury in our study. Most of the patients were discharged on removal of the sutures on 14th post op day.

This study revealed that most of tibial diaphyseal fractures (68%) occurred in young adults ie less than 30 years of age.

In Table 1, the number of subjects is 168, the number of males is 112, and the number of females is 56. Figure 1 shows the distribution of subjects according to gender, with males making up 84% and females 16%.

In Table 2, the duration of union varies from 8 to 14 weeks, and the number of complications ranges from 1 to 8.

DISCUSSION
It is demonstrated that wound complications of MIPO, such as wound infection and implant impingement, in shaft of tibia is common in our study, contrast to other studies saying distal tibia are more common. A study reveals that IMN should be the first method of treatment for the internal fixation for tibia fractures. However, when the fracture line is less than 5cm
proximal to the ankle joint IMN is not applicable. (5) MIPO technique can be an alternative method for those cases IMN is
not available. (8) Various treatment methods have been used for proximal Biological fixation is based on other minimally invasive methods of fixation such as intramedullary nailing. These techniques are newer and technically demanding. Indirect reduction techniques are developed to reduce soft tissue damage at the fracture site and to improve the rate of fracture healing. Thus the good results in this method can be explained by a combination of rapid fracture consolidation due to preserved vascularity and a greatest resistance of the plate to fatigue, since the stress is distributed over a longer length of plate. Our study has focussed on the above treatment modality with use of Dynamic compression plate. Union rate in our study was better than Vander Larsen series (1979) attributed to principles of biological fixation.

CONCLUSION

On the basis of the findings in the study it can be concluded that MIPO is a good choice in treatment of long bone fractures in lower extremities. It can be used either independently or along with external fixation either in closed or open fractures. The application of dynamic compression plate using MIPPO technique does not compromise with the periosteal blood supply thereby causing less interference with the fracture haematoma and the fracture healing.

- There is less incidence of infection due to limited exposure.
- There is no need of any specialised instrumentation and the method is less time consuming and cost effective.
- There are few incidences of delayed and non union.
- This technique can be used in fractures where locked nailing can’t be done like vertical slit and markedly comminated fractures, narrow or very wide medullary canals, fractures with metaphyseal extension and osteoporotic fractures and bad skin condition at the entry portal of I/M nail.
- There is decreased need for bone grafting.
- Plate induced osteoporosis is less frequently seen with dynamic compression plate so there are less chances of refracture after plate removal.
- There is no chance of vascular complication by carefully inserting the plate sub musculously through limited incision.
- Soft tissue complications knee and ankle stiffness are avoided.
- Few cases complained of palpable hardware which can be minimised by using low profile titanium plate.

Hence the procedure is reliable approach towards the management of tibial diaphyseal fractures with proper indications.
