INTRODUCTION

Huang and Zhang [7] have introduced the concept of cone metric space by replacing the set of real numbers by an ordered Banach space and proved many fixed point theorems of contractive type mappings in cone metric space. Subsequently, many authors in [1], [15], [3],[9],[5],[6] have generalised the results of Huang and Zhang and have studied fixed point theorems for normal and non-normal cones. Fixed point theory has now evolved rapidly in cone metric space equipped with partial ordering. In [4], some results regarding partially ordered sets in cone metric spaces have been proved. In [11], [2] some results on the existence of fixed points for non-increasing function in cone metric space as well as an application to ordinary differential equations were found. In [12], some results on existence of a unique fixed point theorem for non-decreasing mappings are applied to obtain a unique solution for differential equation with boundary value problem. In this paper, we prove fixed point theorem for non-decreasing function satisfying generalised condition in cone metric space and also an application to ordinary differential equation was given.

Preliminaries

Definition

Let E be a real Banach space. A subset P of E is called a cone if and only if

1. P is closed, nonempty and P≠ {0}
2. a,b ∈ R, a≥ 0, x, y ∈ P implies ax + by ∈ P
3. p(−p)= {0}

Given a cone P ⊆ E, we define a partial ordering ≤ with respect to P by x ≤ y implies y − x ∈ P. A cone P is called normal if there is a number k≥ 0 such that for all x,y ∈ E, 0≤ x ≤ y implies ||x|| ≤ k||y||.

The least positive number satisfying the above inequality is called normal constant of P, while x ≤ y stands for y − x ∈ int P(interior of P).

Definition

Let X be a nonempty set.Suppose that the mapping d:X × X→ E satisfying

1. 0≤ d(x,y) for all x,y ∈ X and d(x,y) = 0 if and only if x = y
2. d(x,y) = d(y,x) for all x,y ∈ X
3. d(x,y) ≤ d(x,z) + d(z,y) for all x,y,z ∈ X

Then d is called a cone metric in X and (X, d) is called a cone metric space. The concept of a cone metric space is more general than that of a metric space.

**Definition**

Let (X, d) be a cone metric space. We say that \( \{x_n\} \) is

1. A Cauchy Sequence if for every c in E with \( c \gg 0 \), there is N such that for all n, m > N, \( d(x_n, x_m) \ll c \).
2. A Convergent Sequence if for every c in E with \( c \gg 0 \), there is N such that for all n > N, \( d(x_n, x) \ll c \) for some fixed x in X.

A cone metric space X is said to be complete if every Cauchy sequence in X is convergent in X. It is known that \( \{x_n\} \) convergent to x in X if and only if \( d(x_n, x) \to 0 \) as \( n \to \infty \). The limit of a convergent sequence is unique provided \( X \) is a normal cone with normal constant k.

In this paper, we consider a special case of the following periodic boundary value problem

\[
\begin{align*}
  u'(t) &= f(t, u(t)) \quad \text{if } t \in I = [0, T], \\
  u(0) &= u(T).
\end{align*}
\]

where T > 0 and \( f : I \times R \to R \) is a continuous function.

**Definition**

A lower solution for (1) is a function \( \beta \in C(I, R) \) such that \( \beta'(t) \leq f(t, \beta(t)) \) for \( t \in I \) and \( \beta(0) \leq \beta(T) \). The following lemmas are used in main results.

**Lemma 1.**

Let \( P \) be a cone and \( \{a_n\} \) be a sequence in \( X \). If \( c \in int \ P \) and \( \theta \leq a_n \to \theta \) (as n \to \infty), then there exists N such that for all n > N, we have \( a_n \ll c \).

**Lemma 2.**

Let \( x, y, z \in X \) if \( x \ll y \) and \( y \ll z \), then \( x \ll z \).

**Lemma 3.**

Let \( P \) be a cone and \( \theta \leq u \ll c \) for each \( c \in int \ P \), then \( u = \theta \).

**Main results**

**Theorem**

Let (X, d) be a complete cone metric space. Let \( T : X \to X \) be a function satisfying the contractive condition

\[
d(Tx, Ty) \leq a\left(d(x, y) + b\left(d(x, Tx) + d(y, Ty)\right) + c\left[d(x, Ty) + d(y, Tx)\right]\right)
\]

for \( x, y \in X \) and the constants \( a, b, c \in [0,1) \) and \( a + b + c < 1 \). Then \( T \) has a unique fixed point in \( X \).

**Proof**

Let \( x_0 \in X \). Consider \( \{x_n\} \) where \( x_n = Tx_{n-1} \); \( n \geq 1 \), \( x_{n+1} = Tx_n \). From contraction,

\[
d(x_{n+1}, x_n) = d(Tx_n, Tx_{n-1})
\]

\[
\leq a\left(d(x_n, x_{n-1}) + b\left[d(x_n, Tx_n) + d(x_{n-1}, Tx_{n-1})\right] + c\left[d(x_n, Tx_{n-1}) + d(x_{n-1}, Tx_n)\right]\right)
\]

\[
\leq a\left(b + c\right)d(x_n, x_{n-1}) + b\left[a + b + c\right]\left(d(x_n, x_{n-1}) + d(x_{n-1}, x_n)\right)
\]

\[
\Rightarrow d(x_{n+1}, x_n)^{(1-b-c)} \leq d(x_n, x_{n-1})^{(a+b+c)}
\]

Substituting \( c \ll 1 \) as \( n \to \infty \), we have \( d(x_n, x_{n-1}) \ll 1 \).

From Lemma 2.5, we find \( m_0 \in N \), such that

\[
d(x_{m_0}, x_{m_1}) \leq \frac{m_0}{m_1} d(x_{m_1}, x_{m_2}) + \ldots + m_1 d(x_{m_1}, x_{m_0}) + m_0 d(x_{m_0}, x_{m_1})
\]

\[
\leq \left(\frac{1}{m_0}\right)^m d(x_{m_0}, x_{m_1})
\]

For \( \theta \ll c \), \( \frac{m_0}{m_1} d(x_{m_1}, x_{m_2}) + \ldots + m_1 d(x_{m_1}, x_{m_0}) + m_0 d(x_{m_0}, x_{m_1}) \ll \theta \), as \( m \to \infty \).

For each \( m > m_0 \), hence

\[
d(x_{m_0}, x_{m_1}) \ll \left(\frac{1}{m_0}\right)^m d(x_{m_0}, x_{m_1})
\]

for all \( m > m_0 \) and any \( p \). So by lemma \( \{x_n\} \) is a Cauchy sequence in \( (X, d) \). Since \( (X, d) \) is a complete cone metric space, there exist \( x^* \in X \), such that \( x_n \to x^* \).

Let \( k \gg 0 \) be arbitrary. Since \( x_n \to x^* \) there exists N such that

\[
d(x_n, x^*) \ll \frac{k}{N+1} \quad \text{for all } n > N
\]

\[
d(x_n, x^*) \ll \frac{(a+b+c)}{a-1} \quad \text{for all } n > N
\]

Next we claim that \( x^* \) is a fixed point of T.

\[
d(Tx^*, x^*) \leq d(Tx^*, Tx_n) + d(Tx_n, x^*)
\]

\[
= d(Tx^*, Tx_n) + d(x_n, x^*)
\]

\[
d(Tx^*, x^*) \leq a\left(d(x^*, x_n) + b\left[d(x^*,Tx_n) + d(x_n, Tx_n)\right] + c\left[d(x^*,Tx_n) + d(x_n, x^*)\right]\right)
\]

\[
\leq a\left(b + c\right)d(x^*, x_n) + b\left[a + b + c\right]\left(d(x^*, x_n) + d(x_n, x^*)\right)
\]

\[
\Rightarrow d(Tx^*, x^*) \leq k(1-b-c) \leq d(x^*, x_n)(a + b + c) + d(x^*, x_{n+1})(1 + b + c)
\]

\[
\Rightarrow d(Tx^*, x^*) \ll k
\]

From Lemma 3, \( d(Tx^*, x^*) = \theta \), which implies \( x^* \) is a fixed point of T. Finally we need to prove the uniqueness of fixed point.

If there is another fixed point \( y^* \), then
\[ d(x^*, y^*) = d(Tx^*, Ty^*) \leq a \left( d(x^*, y^*) \right) + b \left( d(x^*, Tx^*) + d(y^*, Ty^*) \right) + c \left( d(x^*, Ty^*) + d(y^*, Tx^*) \right) \leq d(x^*, y^*)(a + 2c) \leq d(x^*, y^*)(1 - a - 2c) < 1 \Rightarrow d(x^*, y^*) < 1. \]

Hence from Lemma 3, \( x^* = y^* \).

Therefore, the proof is completed.

**Application to ordinary differential equations**

We consider here a special case of the following periodic boundary value problem

\[ u'(t) = f(t, u(t)) \quad \text{if} \quad t \in I = [0, T], \quad (1) \]

\[ u(0) = u(T). \]

where \( T > 0 \) and \( f : I \times R \rightarrow R \) is a continuous function and suppose that there exists \( \beta > 0 \) such that for \( x, y \in R \) with \( y \geq x \)

\[ -\beta \left( a(x - y) + b \left( (x - Tx) + (y - Ty) \right) \right) + c \left( (x - Ty) + (y - Tx) \right) \leq \left[ f(t, y) + \beta y - f(t, x) + \beta x \right] \leq 0. \]

Then the existence of lower solution \( \alpha \in C(I, R) \) such that \( \alpha'(t) \leq f(t, \alpha(t)) \) for all \( t \in I \) is \( \alpha(T) \leq u(T) \)

for (1) provides the existence of the unique solution to the problem.

**Proof**

The problem can be written in integral equation as

\[ u(t) = \int_0^T G(t, s)\left[ f(s, u(s)) + \beta u(s) \right] ds \]

where \( G(t, s) = \begin{cases} \frac{e^{(T-s)t}}{(T-t)}, & 0 \leq s \leq t \leq T \\ \frac{e^{(T-t)s}}{(T-t)}, & 0 \leq t \leq s \leq T \end{cases} \)

We consider the complete cone metric space \( X = C(I, R) \) with the distance

\[ d(x, y) = \sup \{ x(t) - y(t), x, y \in C(I, R) \}. \]

We define the following order relation in \( M = C(I, R) \) by \( x, y \in C(I, R) \), \( x \leq y \) if and only if \( x(t) \leq y(t) \), for all \( t \in I \).

We define \( H : C(I, R) \rightarrow C(I, R) \) by

\[ [Hu(t)] = \int_0^T G(t, s)\left[ f(s, u(s)) + \beta u(s) \right] ds \]

If \( u \in C(I, R) \) is a fixed point of \( H \), then \( u \in C^1(I, R) \) is a solution of (1) for \( u \geq v \),

\[ [Hu(t)] = \int_0^T G(t, s)\left[ f(s, u(s)) + \beta u(s) \right] ds \geq \int_0^T G(t, s)\left[ f(s, u(s)) + \beta v(s) \right] ds = [Hv(t)] \]

Then \( H \) is increasing. For \( u \geq v \) we get

\[ d(Hu, Hv) = \sup \{ Hu(t) - Hv(t) \} \leq \sup \{ G(t, s)\left[ f(s, u(s)) + \beta u(s) - f(s, v(s) + \beta v(s)) \right] ds \sup \{ G(t, s)\left[ f(s, u(s)) + \beta u(s) - f(s, v(s) + \beta v(s)) \right] ds \leq \frac{\beta}{\alpha} [ad(u, v) + b(d(u, Tu) + d(v, Tv)] + c(d(u, Tv)) \]

and a lower solution to the problem is such that \( \beta(t) \leq \frac{\beta}{\alpha} \left[ H(\beta) \right](t), \quad t \in I \).

From theorem, finally \( H \) has a unique fixed point.
